Experiment Proposal for PAC48:

The Two-Photon Exchange Contribution in Elastic $e-n$ Scattering

On behalf of the nTPE spokespeople;
Sheren Alsalmi - King Saud University
Eric Fuchey – University of Connecticut (Speaker)
Bogdan Wojtsekhowski- Jefferson Lab

Jefferson Lab PAC48
August 10th, 2020
In the **One-Photon Exchange** (Born) approximation:

\[
\left( \frac{d \sigma}{d \Omega} \right)_{eN \to eN} = \frac{\sigma_{\text{Mott}}}{\epsilon (1 + \tau)} \left[ \tau G_M^2(Q^2) + \epsilon G_E^2(Q^2) \right]
\]

with \( \tau = Q^2 / (4 M_N) \)

Rosenbluth technique: separate \( G_M^2 \) and \( G_E^2 \) based on the linear dependence in \( \epsilon = \left[ 1 + 2(1 + \tau) \tan^2 \theta / 2 \right]^{-1} \)

\[
\sigma_r = \left( \frac{d \sigma}{d \Omega} \right) \cdot \epsilon (1 + \tau) / \sigma_{\text{Mott}} = \tau G_M^2(Q^2) + \epsilon G_E^2(Q^2) = \sigma_T + \epsilon \sigma_L
\]

Two or more measurements, same \( Q^2 \), different \( E \) and \( \theta \) (different \( \epsilon \))

---

**Elastic \( e-N \) Scattering, Rosenbluth (1950)**

![Diagram of Elastic \( e-N \) Scattering](image)

\( 08/10/2020 \)
Technique extensively used to measure Rosenbluth slope for the proton and extract $G_E^p$

Linearity in $\epsilon$ well tested up to $Q^2 \leq 3$ (GeV/c)$^2$
Elastic $e$-$n$ measurements at 1-2 (GeV/c)$^2$ (1960’s and 70’s)

\[(G_E^n)^2 = S^n \times \tau (G_M^n)^2\]

Accuracy achieved in $e$-$n$ measurements 50 years ago is not sufficient to measure the Rosenbluth slope.
At $Q^2 = 4.5$ (GeV/c)$^2$, the Rosenbluth slope is $S^p = \sigma_L^p / \sigma_T^p \approx 0.087 \pm 0.01$.

Rosenbluth and polarization transfer methods have a large discrepancy.

Missing contribution, likely to be due to two-photon exchange (TPE).
Mechanism of $e-N$ scattering (proton)

- Until GEp-I at Jefferson Lab, Phys. Rev. Lett. 84, 1398 (2000), OPE accepted to be a sufficient approximation
- Investigation of two-photon exchange is mandatory
- Many experiments were dedicated to measure two-photon exchange (TPE), including Rosenbluth and $e^\pm-p$ scattering
- Linearity at mid $\epsilon$ does not exclude TPE

Fit from polarization transfer $G_E^p/G_M^p$ data
- same, corrected with TPE contributions

measurement on neutron will bring new insight to this physics
Two-Photon Exchange (TPE) contribution never measured for the neutron.

Blunden, Melnitchouk and Tjon, Phys. Rev. C72, 034612 (2005) gave a prediction of the impact of the TPE correction on $G_E^n/G_M^n$ using Rosenbluth separation method.

![Graph showing corrected and uncorrected $\mu_n G_E^n/G_M^n$ values for different $Q^2$ values with TPE contributions at different values of $\epsilon$.](image)
Proposed experiment

**Goals:**

- Measure the Rosenbluth slope for elastic $e-n$ scattering for the first time since 1972, with 10 times improved accuracy
- Extract the two-photon exchange contribution on elastic $e-n$ scattering

**Means:**

Use equipment and data from approved experiment E12-09-019 (GMn) in Hall A

Plan view of $Q^2 = 4.5 \text{ (GeV/c)}^2$, $\epsilon = 0.6$ kinematic setting

Dimensions mm

**Beam**: 6.6 GeV (3 pass), 30 $\mu$A

**Target**: 15 cm liquid $D_2$

**Electron arm**: BigBite

**Hadron arm**: SBS
Key experimental parameters

• Electron-nucleon luminosity: $2.8 \times 10^{38} \text{ cm}^{-2}/\text{s}$

• BigBite: $\Delta \Omega = 32 \text{ msr}$; $\Delta p/p = 1.0\%$, $\Delta \theta = 1.2 \text{ mrad}$, $\Delta \phi = 2.0 \text{ mrad}$.

$\Rightarrow$ resolution in $W^2 = M_N^2 + 2M_N(E-E') - Q^2$ of the quasi-elastic peak: 0.25 GeV$^2$

- MC: quasi elastic $e-N$
- MC: inelastic resonant $e-N$

• Calorimeter threshold: $3.0 \text{ GeV}$ for 4.2 GeV mean elastic peak.

$\Rightarrow$ Projected single rates for BigBite: $8 \text{ kHz}$
Key experimental parameters

- SBS: $\Delta \Omega_{SBS} = 71 \text{ msr}; \Delta \theta = \Delta \phi = 5 \text{ mrad}, \Delta t / t = 0.5 \text{ ns} / 25 \text{ ns}, \Delta E/E = 0.4$

Nucleon identification by reconstructed vs projected position in HCal

- Calorimeter threshold: 0.10 GeV for 90% efficiency of the 3.2 GeV/c nucleons which deposit 0.20 GeV in the HCal (scintillator material)

  => Projected single rates for SBS: 3.3 MHz

- Projected trigger rates (30 ns coincidence window with BigBite): 820 Hz

  Projected quasi-elastic rates: 180 Hz (45 Hz e-n + 135 Hz e-p)
Simultaneous elastic $e-n/e-p$ measurement off deuterium: measure $\sigma_{en}/\sigma_{ep}$

- Cancellation of nucleon momentum/binding effects in $\sigma_{en}/\sigma_{ep}$ ratio;
- Other effects are partially cancelled and the $\sigma_{en}/\sigma_{ep}$ ratio
  - Nucleon charge exchange in final state interactions
  - Inelastic $e-N$ contamination

**Durand technique extensively used to measure $G_M^n$ recently at JLab and Mainz**
• Using Durand technique (discussed for $G_E^n$ at JLab at High-t (2002))

\[ R_{n/p} \equiv R_{\text{observed}} = \frac{N_{e,e^n}}{N_{e,e^p}} \]

• Given $f_{\text{corr}}$ (including RC, hadron efficiencies, etc) we have $R_{\text{corrected}} = R_{n/p} \times f_{\text{corr}}$

which can also be written:

\[ R_{\text{corrected}} = \frac{\sigma_n}{\sigma_p} \frac{1 + \tau_p}{1 + \tau_n} \frac{\sigma_n + \epsilon \sigma_L^n}{\sigma_T^n + \epsilon \sigma_L^n} = \frac{\sigma_T^n + \epsilon \sigma_L^n}{\sigma_T^p + \epsilon \sigma_L^p} \]

• Measurements for two $\epsilon$ points: $R_{\text{corrected}, \epsilon_{i,2}} = R_{Mott, \epsilon_{i,2}} \left( \frac{\sigma_n + \epsilon_1 \sigma_L^n}{\sigma_T^n + \epsilon_1 \sigma_L^n} \right) / \left( \frac{\sigma_T^n + \epsilon_1 \sigma_L^n}{\sigma_T^p + \epsilon_1 \sigma_L^p} \right)$

• Using $A = R_{\text{corrected}, \epsilon_1} / R_{\text{corrected}, \epsilon_2}$ the experimental observable and

\[ B = \left( R_{Mott, \epsilon_1} / R_{Mott, \epsilon_2} \right) \times \left( 1 + \epsilon_2 S_p \right) / \left( 1 + \epsilon_1 S_p \right) \]

with $S_p = \sigma_L^p / \sigma_T^p \approx 0.087 \pm 0.01$ we find

\[ A = B \times \left( 1 + \epsilon_1 S^n \right) / \left( 1 + \epsilon_2 S^n \right) \approx B \times \left( 1 + \Delta \epsilon S^n \right) \]

with $\Delta \epsilon = \epsilon_1 - \epsilon_2 \Rightarrow S_n = \frac{A - B}{B \Delta \epsilon}$
As E12-09-019 we use $e-n/e-p$ ratio to measure electron-neutron cross section. **Dominant sources of systematic uncertainties are cancelled out.**

Remaining sources of systematic uncertainties come from $S^p$, $\mu_n\left(\frac{G_E^n}{G_M^n}\right)$

Expected Result

Assuming the same proportions of TPE and $G_E^n$ contributions to $S^n$ as in Blunden, Phys. Rev. C72, 034612 (2005), but using $G_E^n$ from the review, Perdrisat et al. Eur. Phys. J. A51, 19 (2015), we expect the nTPE contribution to be: $0.063 \pm 0.010$ (stat) $\pm 0.012$ (syst)

**Straightforward insertion of the experiment in the approved E12-09-019 schedule**

08/10/2020
Conclusions

- The knowledge on Two-Photon Exchange (TPE) contribution is essential to shape our understanding of the elastic electron nucleon scattering and hadron structure.
- This experiment will provide the first Rosenbluth measurement of elastic $e-n$ scattering since 1972, with 10x improved accuracy, at higher $Q^2 = 4.5 \text{ (GeV/c)}^2$
- Result will help advancing theoretical understanding of TPE.
- Straightforward insertion of the experiment in the current Hall A E12-09-019 (GMn) schedule, with two PAC days requested.
Backup
Collaborators

Motivation: **Form Factors** provide key information about partonic structure

Issue: Discrepancy between Rosenbluth and polarization transfer methods for $G_E/G_M$ in $e-p$ is not fully resolved => TPE likely resolves this discrepancy

We propose to measure **elastic $e-n$ with Rosenbluth separation**

How to achieve it: high luminosity ($2.8 \times 10^{38}$ cm$^{-2}$/s) with large solid angles

=> **10 times improved accuracy** than in 1972 measurement

Requested beam time for experiment: **2 PAC days**

Projected result: $S^n = 0.126 \pm 0.010 \pm 0.010$, actual central value is unknown
1. Proton and neutron charge exchange will bias the ratios to be measured in this experiment. The significance of this effect could be estimated with an Eikonal-based calculation.

We are collaborating with M. Sargsian. His preliminary estimate of the FSI correction to the $D(e,e'p)$ cross section at our experimental kinematics is about 5% or less. Misak also pointed out that the uncertainty in the calculation of this correction is small and the resulting uncertainty is below 0.5% for the cross section. In addition, for the ratio $D(e,e'n)/D(e,e'p)$ the correction is even smaller.

See the recent paper by M. Sargsian about $D(e,e'p)$: Int. JME E 24, 1530003 (2015). Misak also offered us his guidance in the use of his Eikonal-based code.

Calculations for FSI in nucleon electrodisintegration by Misak Sargsyan are presented in Phys. Rev. C82, 014612 (2010). The accuracy of this calculations have been experimentally validated in W. Boeglin et al. Phys. Rev. Lett. 107, 262501 (2011)
3. There are no technical issues in this proposal beyond those of the E12-09-019 GMn experiment. The same detectors, spectrometers, target, measurement techniques, data acquisition etc. will be used. The only item of note is that the proposed BigBite spectrometer angle of 23.2° is smaller than the smallest angle planned for the GMn measurements (32.5°), but neither reaching that angle nor the expected data rates in either of the spectrometers at that setting, after trigger threshold adjustment, are of concern. In fact, the coincidence trigger rate for the proposed high-ε data point is expected to be lower than that of the corresponding low-ε point of the GMn program.

The small angle of the BigBite central ray and the magnet location used in our MC simulation are consistent with the Hall A design.
A further question is about the calculation of RCs, including TPE, for the quasi-elastic $eD$ scattering and their relation to the RCs for a free neutron. Some of the applicable corrections for the quasi-elastic reaction would involve, for example, one photon exchanged between the electron and proton and one between the electron and neutron, which would not be present in elastic scattering from a free neutron or proton. Are such effects included in the RCs contained in the $f_{corr}$ in Eq. (6)?

Yes, this effect is included in the radiative correction procedure. Such an inclusion is possible for our data due to the kinematical cuts which will be applied to the missing momentum, $p_{\perp \text{miss}}$, a difference between the high energy nucleon momentum and electron missing momentum. The projected accuracy for $p_{\perp \text{miss}}$ (+/- 10 MeV/c) allows us to limit the momentum of a second photon (in the TPE diagram with two nucleons) to below 100 MeV/c.
From the calculations in Ref. [4], it’s clear from Fig. 12 there that the TPE correction $\delta$ decreases with increasing $\varepsilon$, approaching zero as $\varepsilon \to 1$. From the perspective of obtaining a more robust slope of the cross section versus $\varepsilon$, it would be significantly preferable if measurement at a smaller $\varepsilon$ value were possible. The range between $\varepsilon = 0.6$ and 0.84 is relatively small, and given the predicted spread in the TPE corrections over this range, the measurement would need to be extremely precise in order to clearly observe the sought-after signal.

We agree that the measurement at lower $\varepsilon$ will be a very useful addition to the proposed plan. However, it requires a non-standard beam energy of 3.3 GeV which is difficult to get due to the impact on the other three halls’ operation and time consuming reconfiguration of the accelerator.

Non standard beam energy at JLab
**Event selection:**
- Electron track reconstructed in BigBite;
- Total energy deposited in BigBite calorimeter > 3 GeV threshold (average 4.2 GeV elastic peak, slide 10);
- Electron track must fire at least 3 PMTs in the GRINCH detector;
- Total energy deposited in HCal > 0.10 GeV threshold. (90% efficiency of the 3.2 GeV/c nucleons deposit 0.20 GeV in the HCal scintillator material, slide 11).

**$W^2$ reconstruction** (slide 10), **selection cut $W^2 < 1.10$ GeV$^2$**

expected 3% inelastic contamination of quasi elastic sample after $W^2$ cut.
• **Nucleon projection on HCal assuming:**
  * nucleon is a neutron (unaffected by SBS);
  * \( \vec{p}' = \vec{q} \) (with \( p' \) the nucleon momentum and \( q \) the virtual photon momentum)
  
  \( \Rightarrow \) **Nucleon identification** (slide 11)

• **Nucleon momentum reconstruction** in SBS coordinates system:

  \[
  p'_{x,\text{SBS}} = p'(x_{\text{rec}} - v \sin \theta_{\text{SBS}})/(D_{\text{HCal}} - v \cos \theta_{\text{SBS}}) \quad p'_{y,\text{SBS}}(n) = p'(y_{\text{rec}})/(D_{\text{HCal}} - v \cos \theta_{\text{SBS}})
  \]

  \[
  p'_{y,\text{SBS}}(p) = p'(y_{\text{rec}} + \Delta y_p)/(D_{\text{HCal}} - v \cos \theta_{\text{SBS}}) \quad (\Delta y_p \text{ calculated for each event})
  \]

  then translated back to Hall A coordinates system.

• **Transverse missing momentum construction:**

  \[
  p_{\perp \text{miss}} = \sqrt{(q_x - p'_x)^2 + (q_y - p'_y)^2}
  \]

  Selection cut on
  
  \( p_{\perp \text{miss}} < 0.1 \text{ GeV/c} \)

  \( \Rightarrow \) <1% inelastic contamination of quasi elastic
Calorimeter threshold: **0.10 GeV** for 90% efficiency of the 3.2 GeV/c nucleons which deposit 0.20 GeV in the HCal (scintillator material)

=> Projected single rates for SBS: **3.3 MHz**

If rates are significantly higher than expected: HCal threshold raised to 0.15 GeV

=> the elastic nucleon efficiency will drop to 74% (~20% relative drop);

=> singles will drop by a factor 2.5;

\[
\text{Thr 0.10 GeV:} \quad 90\% \text{ eff. QE,} \\
\text{3.3 MHz singles}
\]

\[
\text{Thr 0.15 GeV:} \quad 74\% \text{ eff. QE,} \\
\text{1.3 MHz singles}
\]
